

Scalpel Erasmus 2nd online session

3rd May 2022

Prof. Smrcka M., M.D., Ph.D., MBA
Mrlian A., M.D., Ph.D.
University hospital Brno
Fakulty of Medicine Masaryk University Brno

**Co-funded by
the European Union**

Hydrocephalus

- Definition
- Childhood vs. Adulthood (acquired + NPH)
- Acute vs. Chronic
- CSF functions
- Symptoms

Hydrocephalus

- Diagnostics

- 1.Clinical and neurological exam
- 2.Tap test
- 3.Brain imaging
- 4.Lumbar puncture and/or drainage

Derivative procedures in hydrocephalus (HCP)

Treatment of hydrocephalus

- observation
- conservative treatment
- surgery
 - temporary (acute HCP)
 - external ventricular drainage
 - external lumbar drainage
 - permanent (chronic HCP)
 - shunt
 - neuroendoscopy
 - other
(Torkildsen drainage etc.)

Case 1

- female, 67 years
- sudden onset – confusion, impairment of speech
- duration of symptoms: 10-15 min.
- no other symptoms
- physical exam negative

Case 1

Case 1

- TIA
- congenital hydrocephalus
- no symptomps = no treatment

Case 2

- male, 60 years
- sudden onset of headache (unknown so far), vomiting
- meningeal signs, no focal neurological deficit
- Consciousness disorder

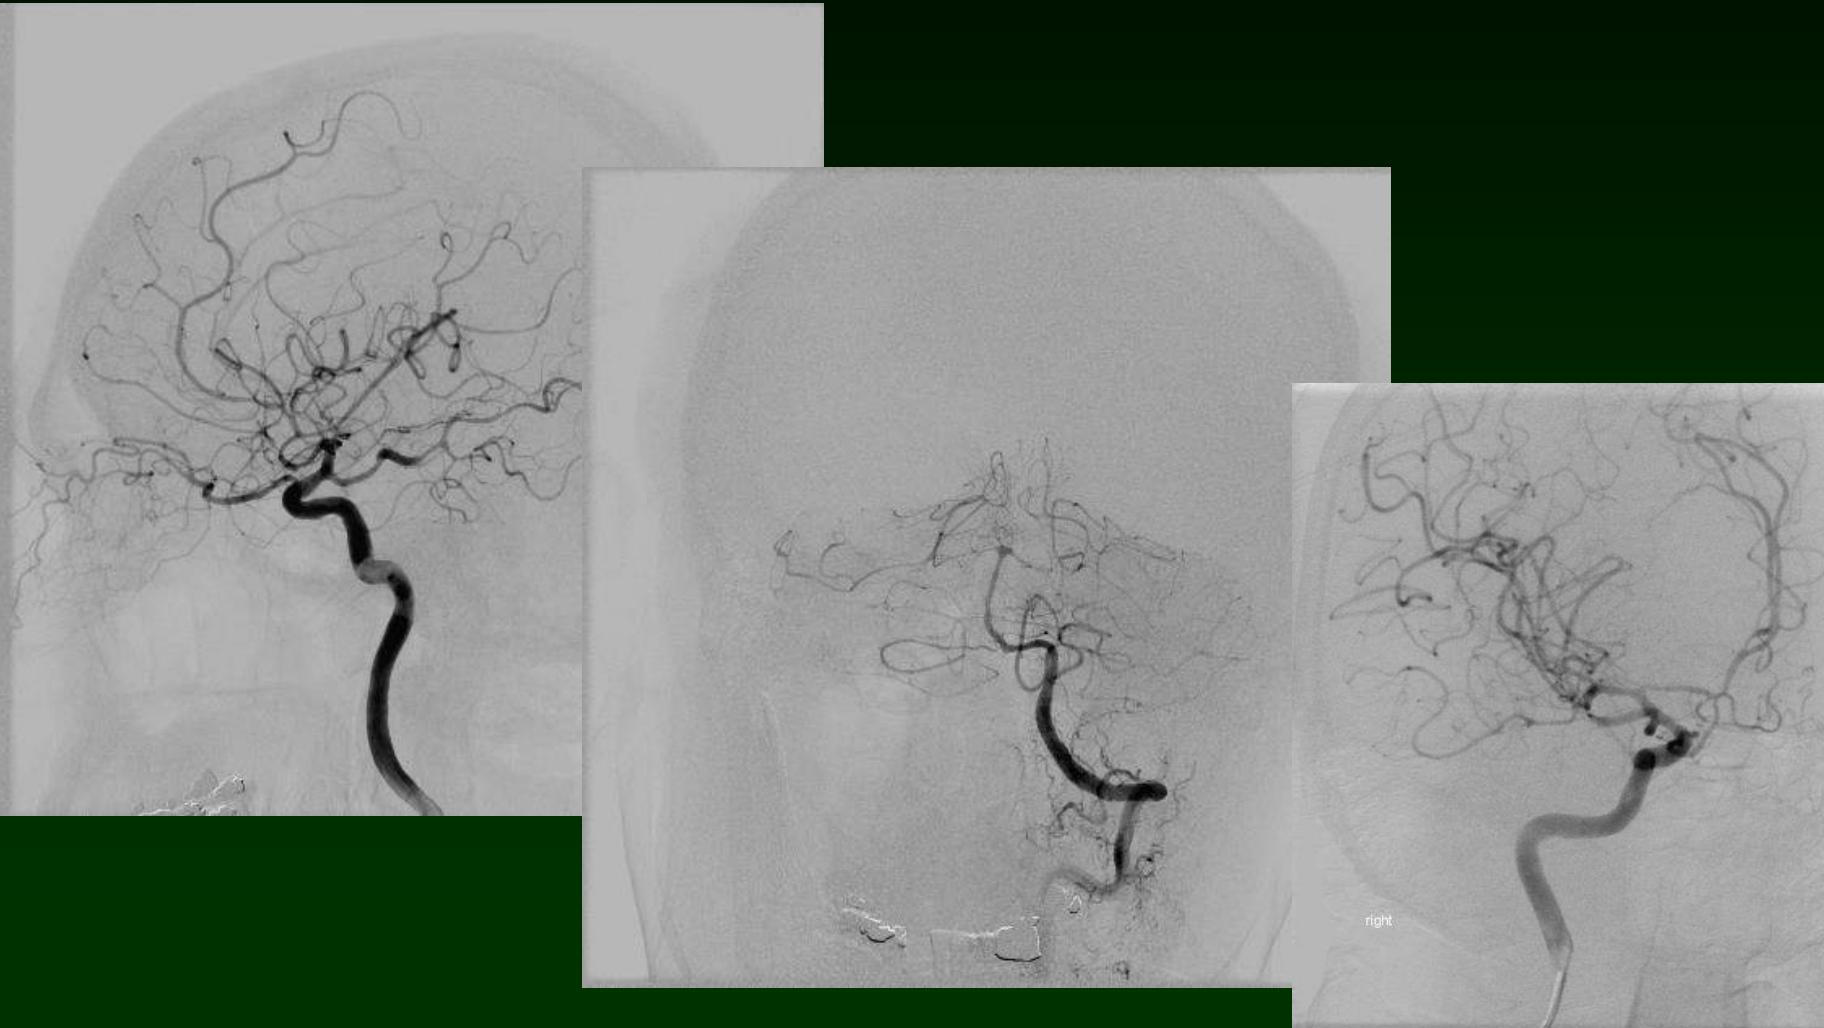

Case 2

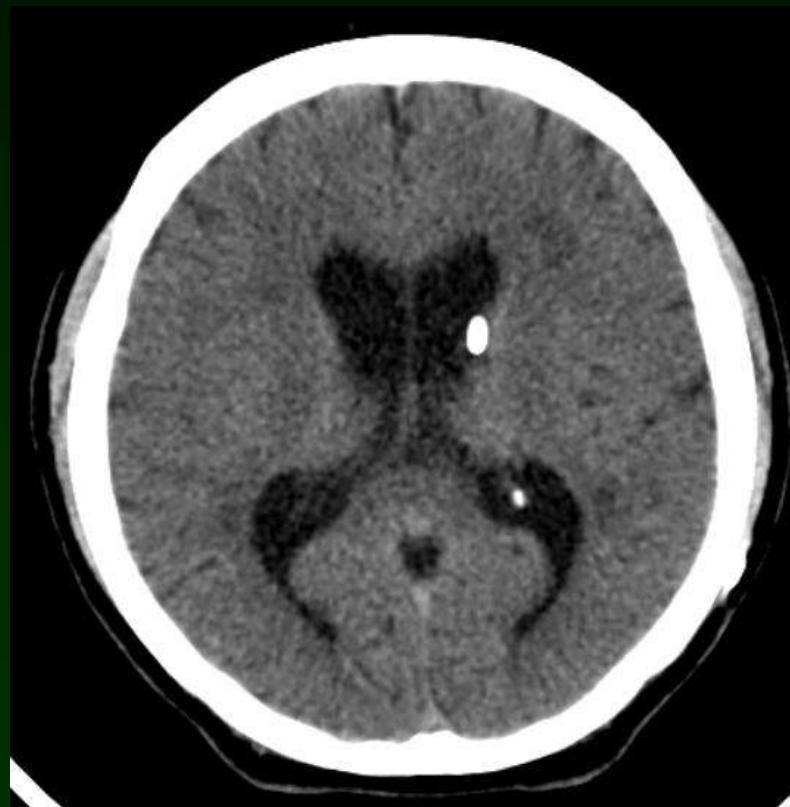

Case 2

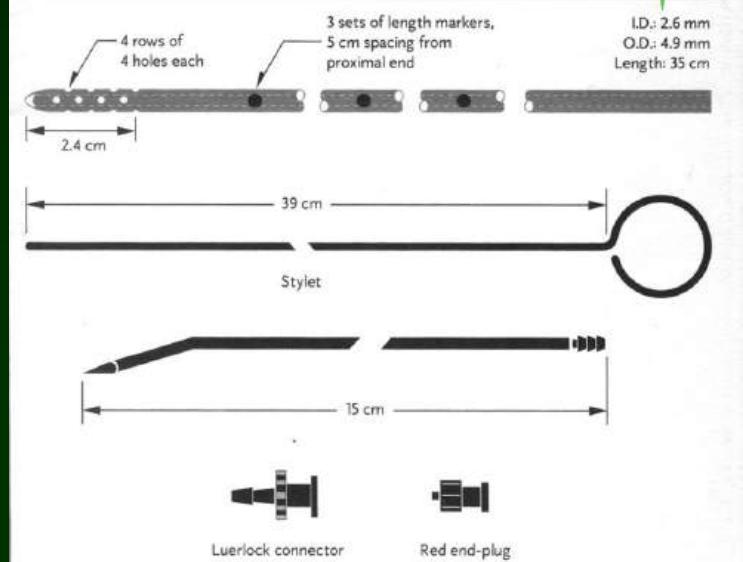

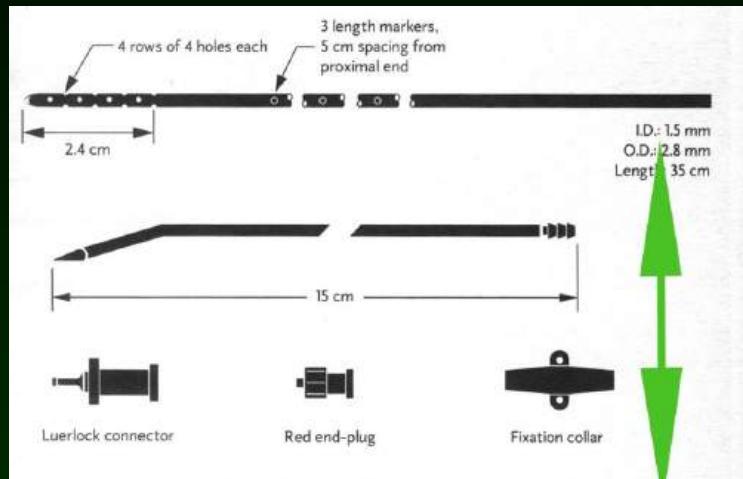

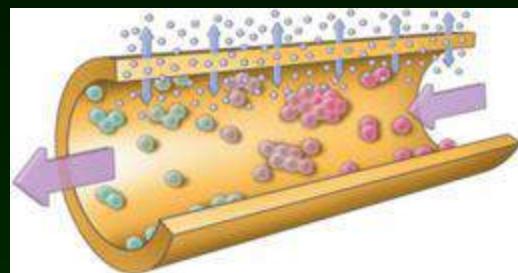

Case 2

Case 2

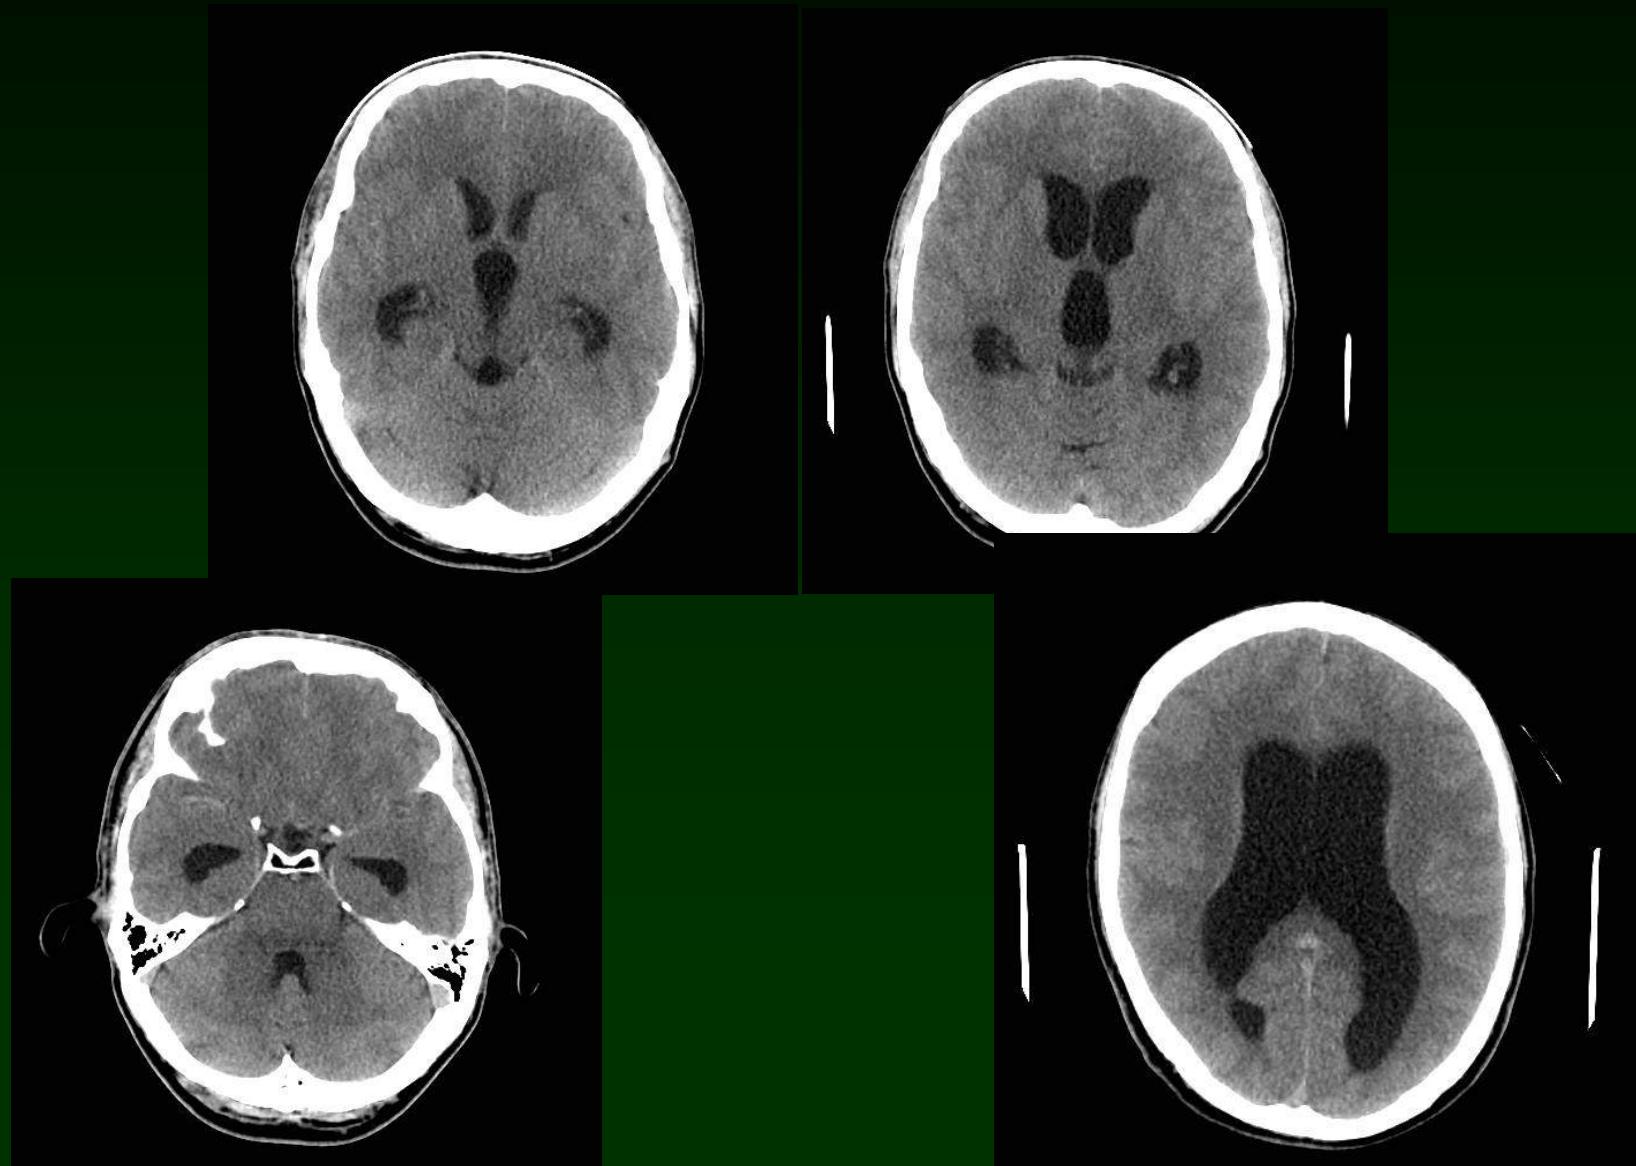

Case 2

Case 3

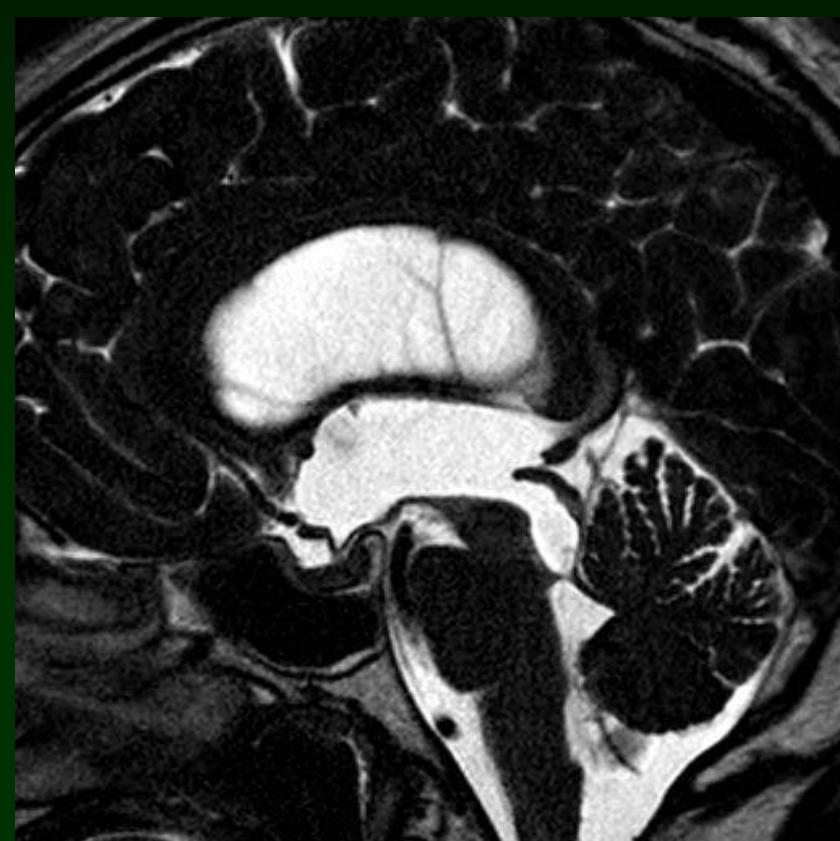

- male, 40 years
- sudden onset – headache, nausea, vomiting
- CT exam – hydrocephalus
- ophthalmoscopy – the edges of the optic disc unclearly defined
- psychomotor slowing, dystaxia, no meningeal signs

Case 3

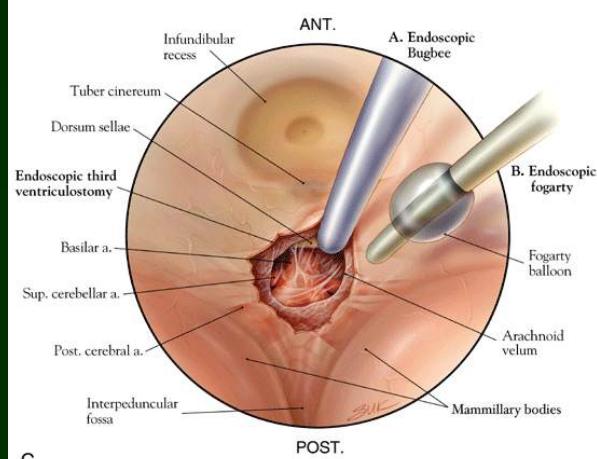

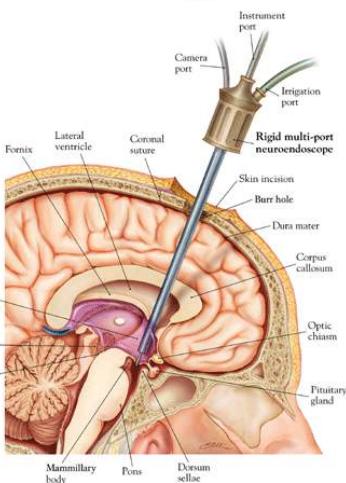

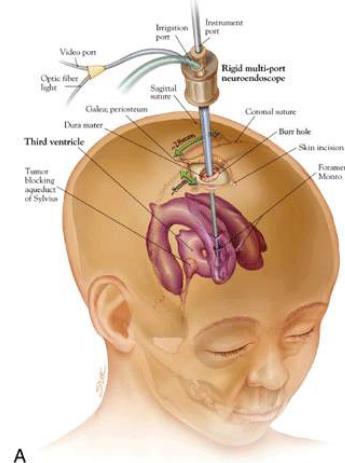

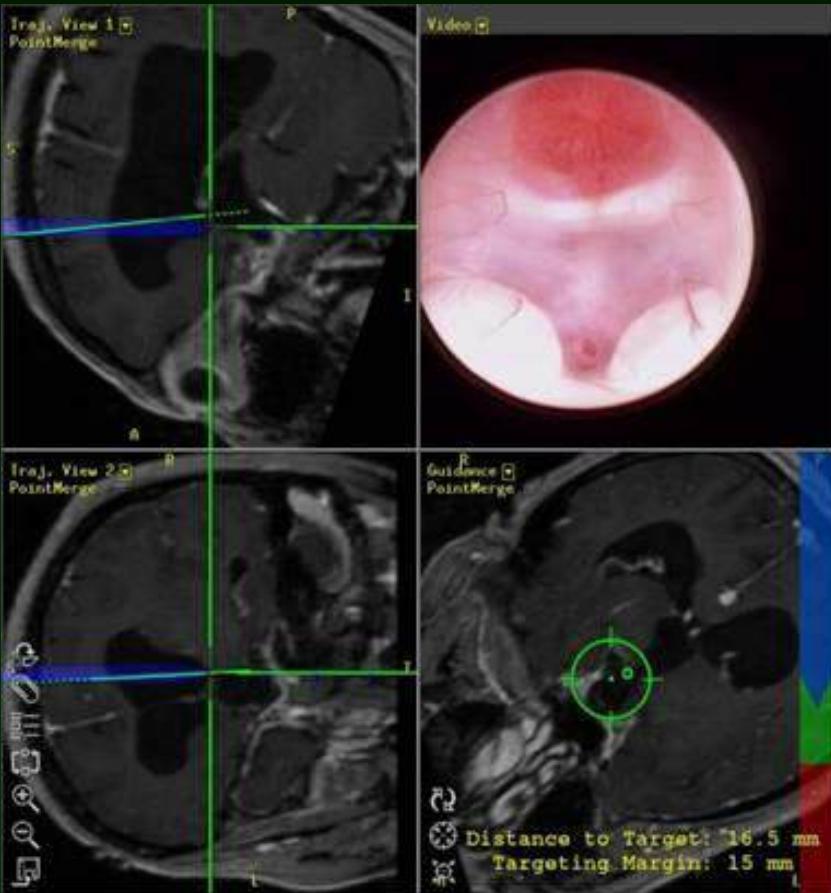

Case 3

- external ventricular drainage
- MRI

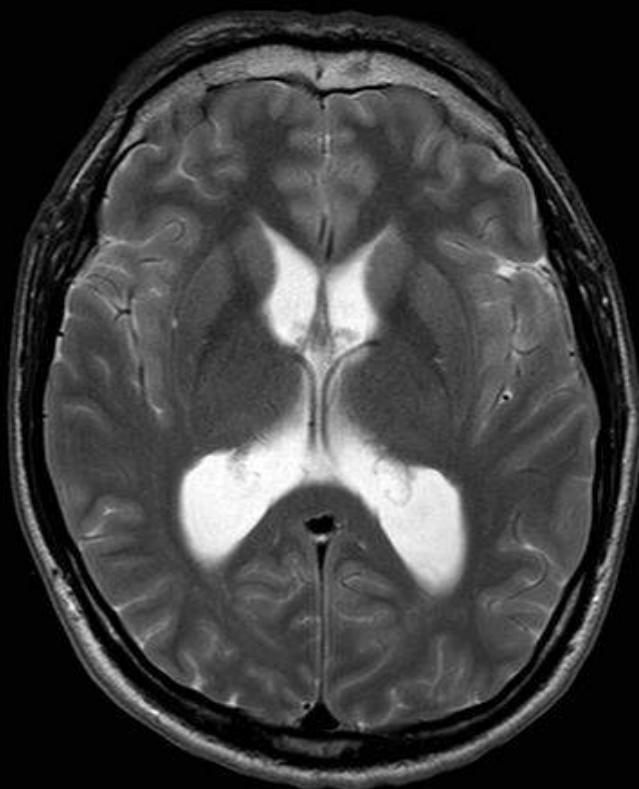

Case 3

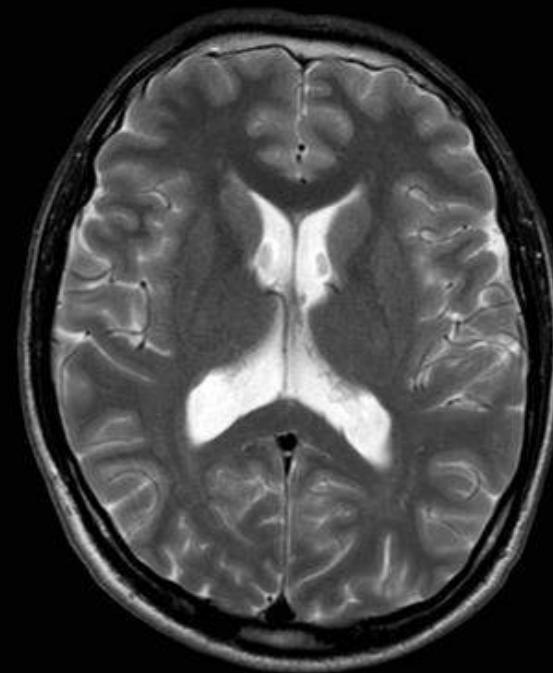

- 3rd ventriculostomy

Case 3

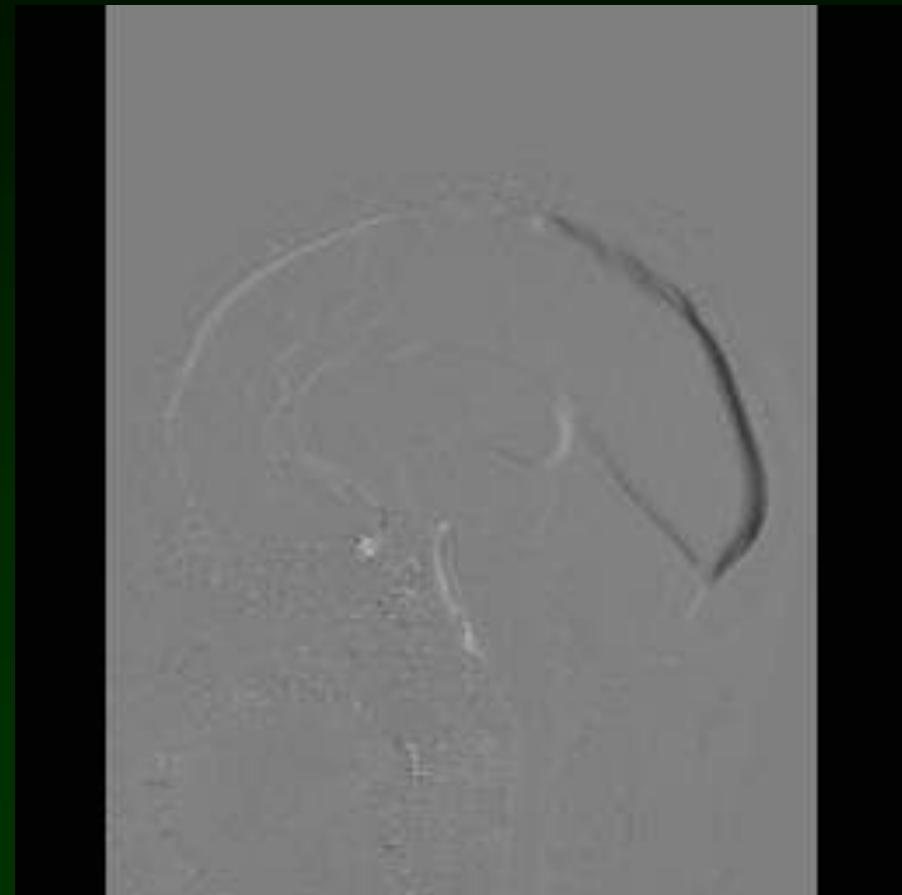

Before OP

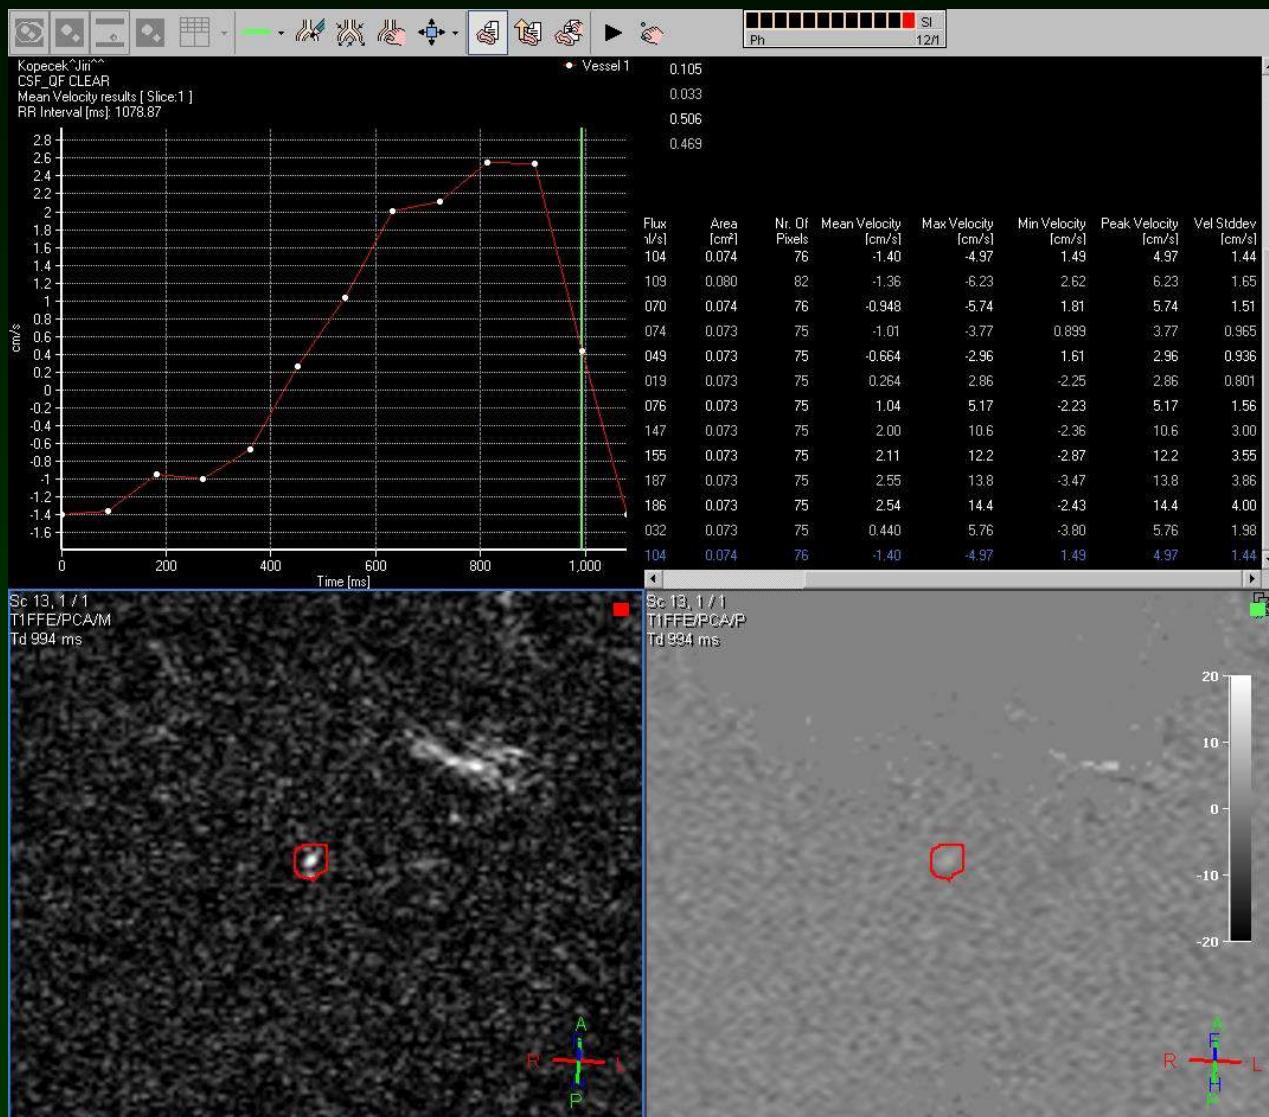

After OP

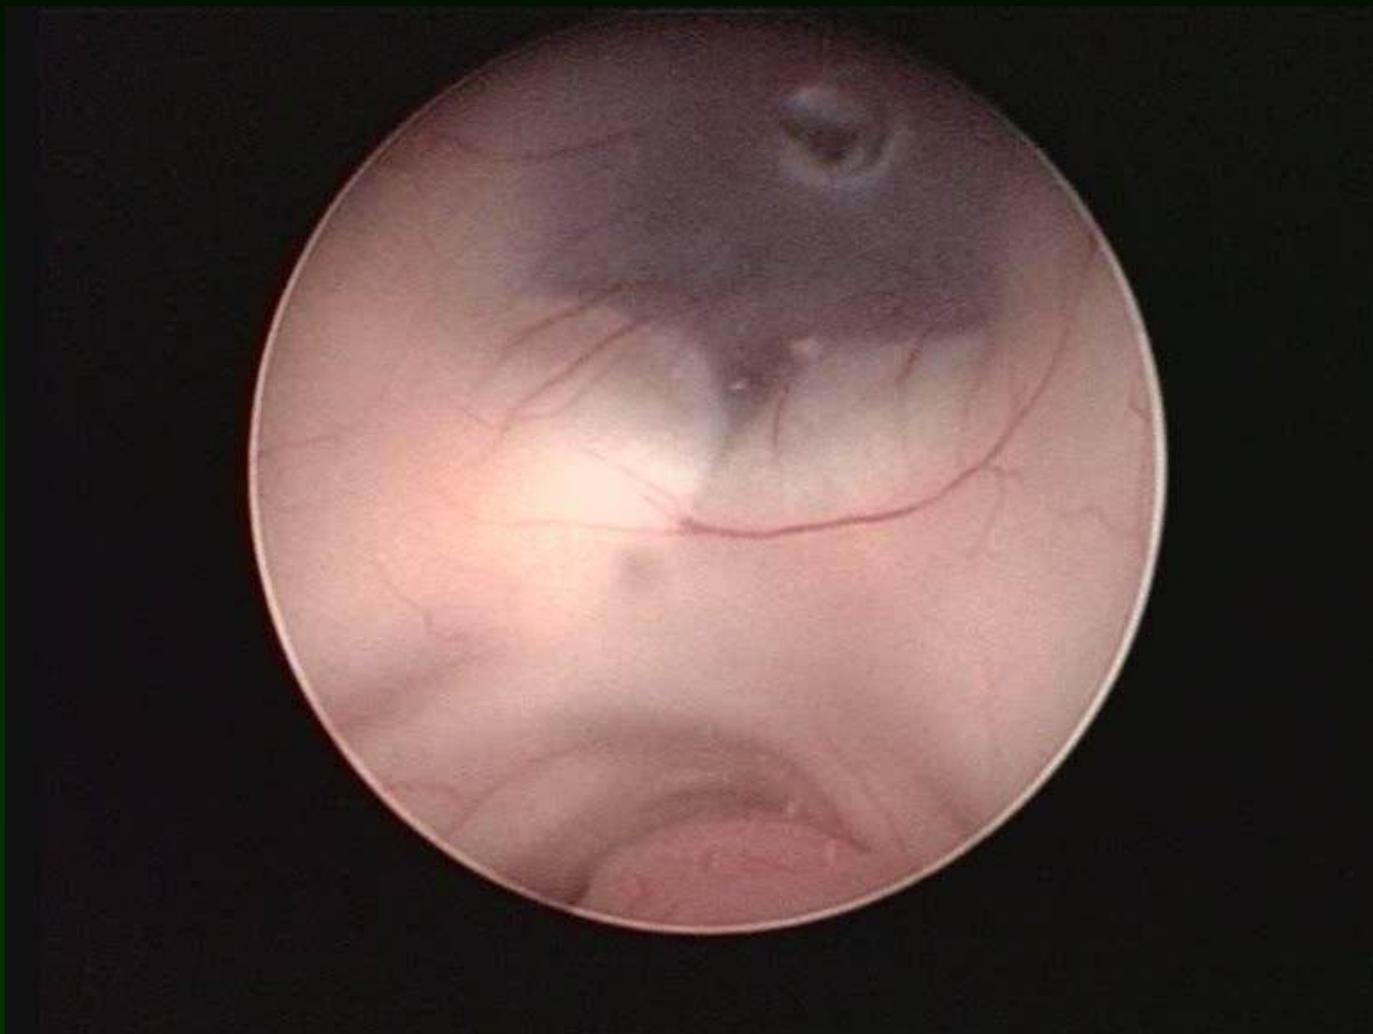

Case 3

Case 3

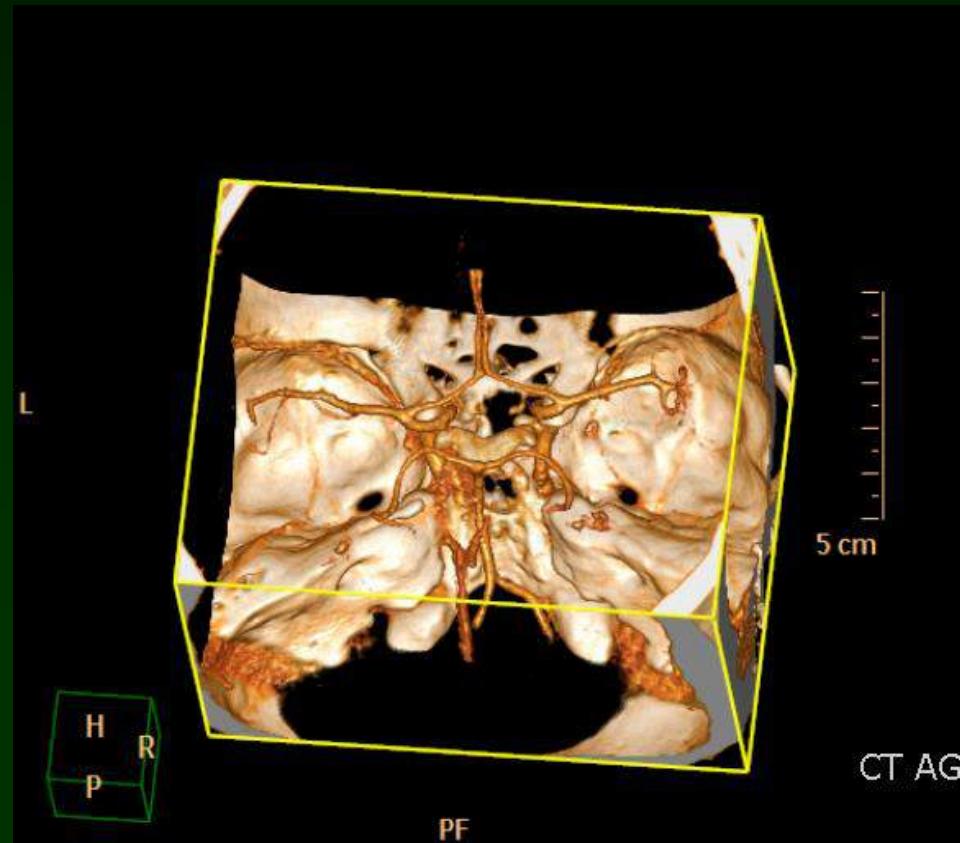

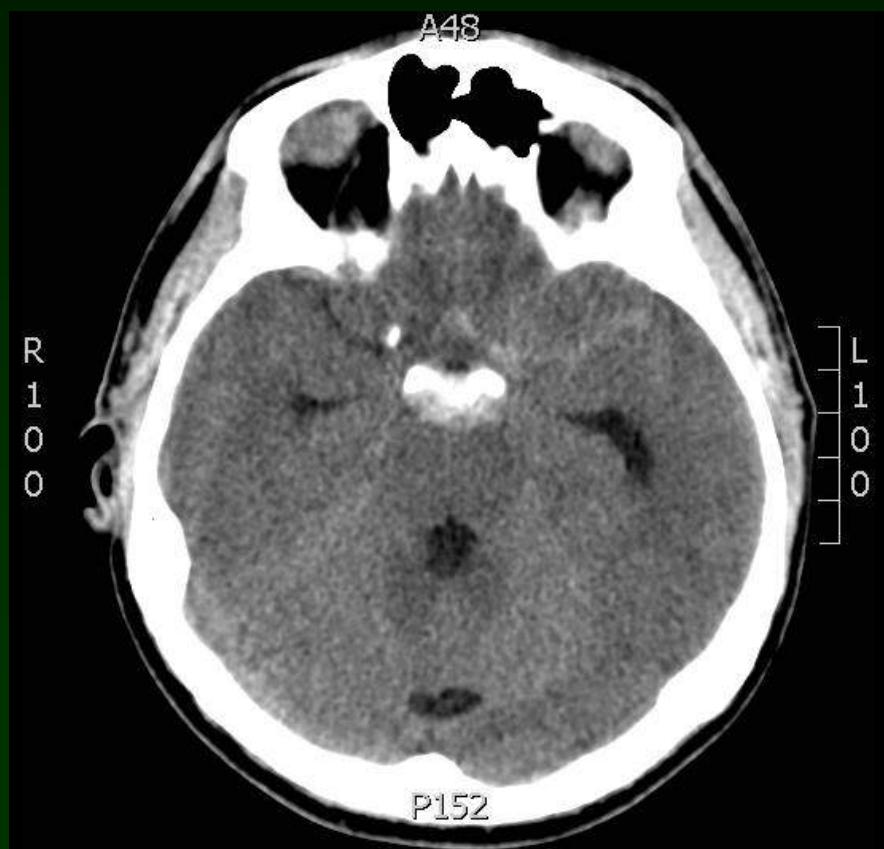

Case 3

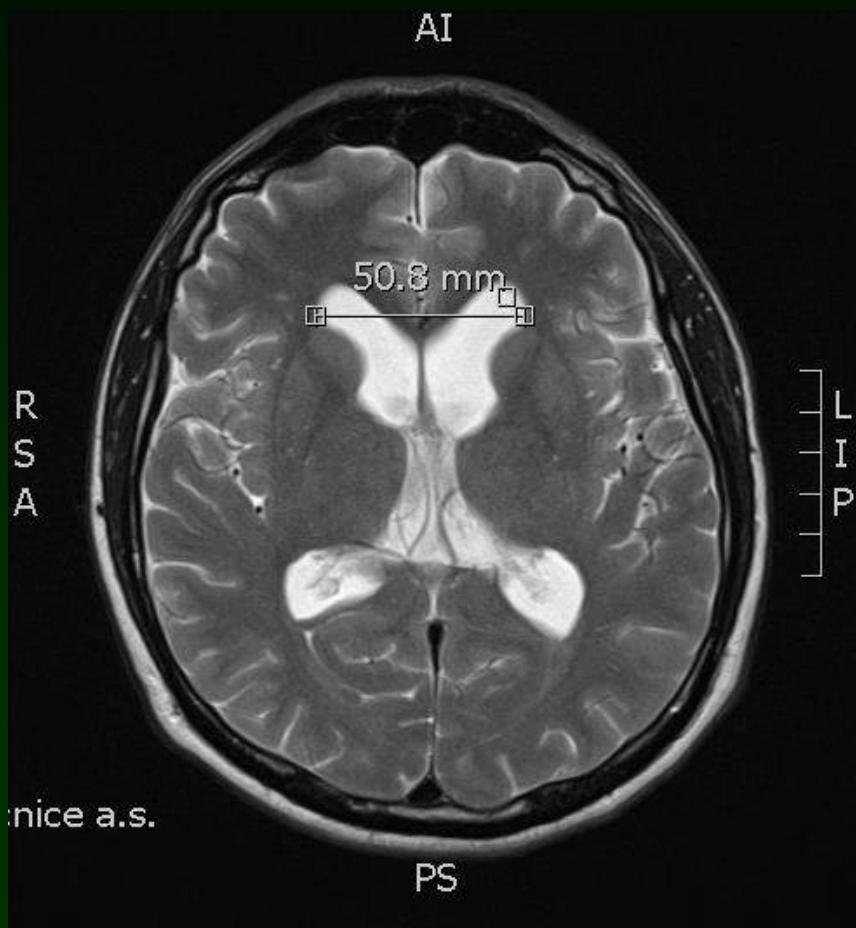

Case 4

- male, 48 years, acute SAH

Case 4

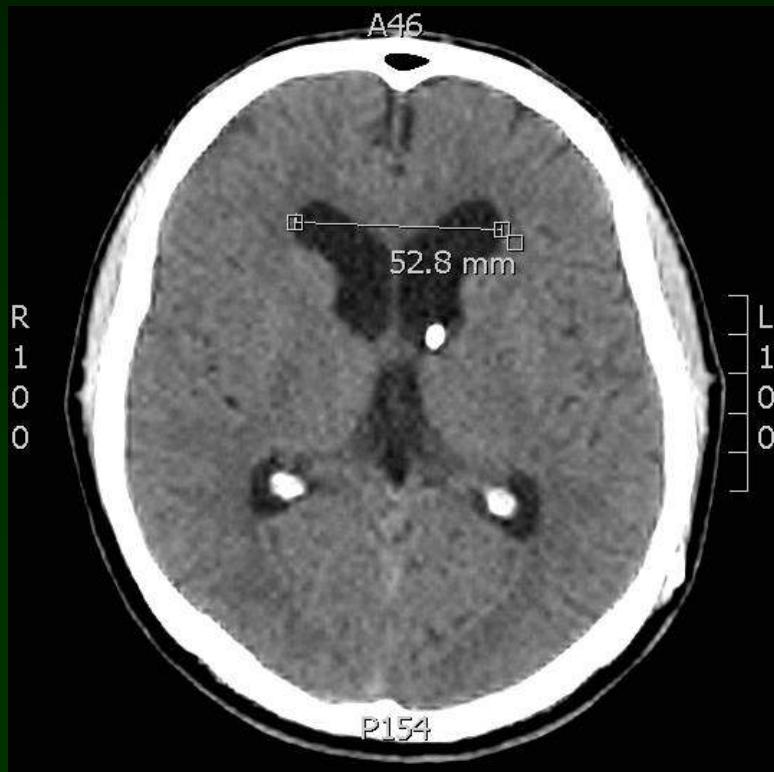

1 month after SAH

5 months after SAH

Case 4

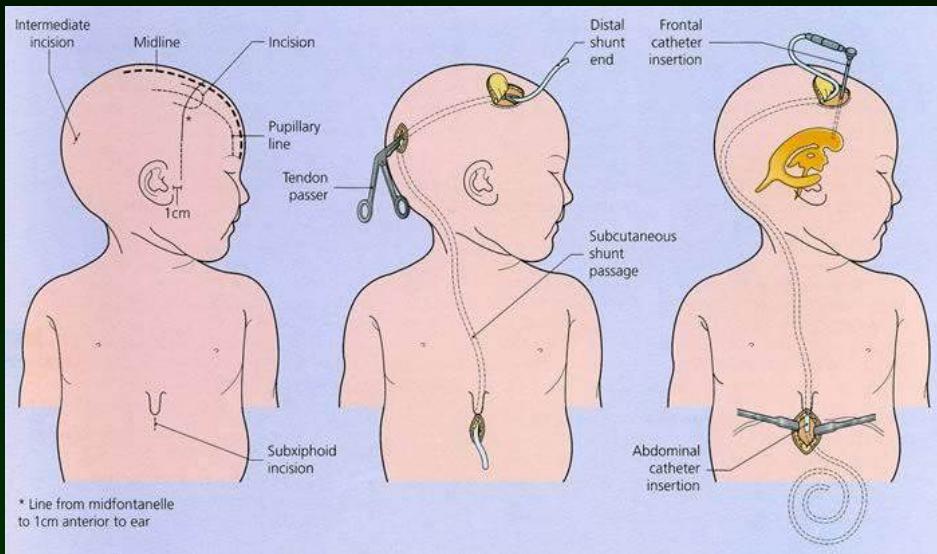

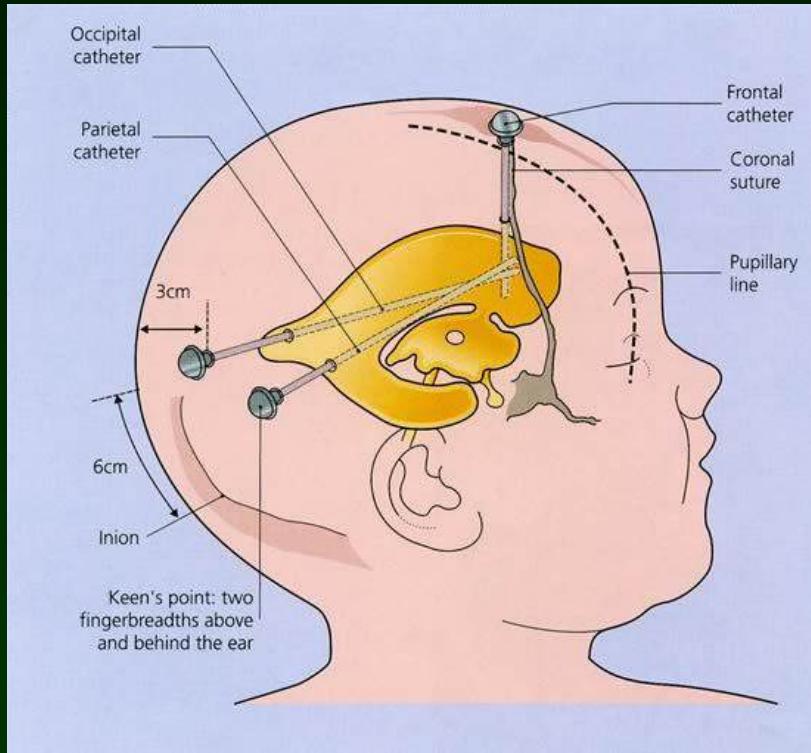

- 5 months after SAH
- headache, memory disorder

4 days after surgery

Case 4

- VP shunt

Case 5

- female, 55 years, SAH, aneurysm BA, coiling
- hydrocephalus
- implantation of a VP shunt
- shunt malfunction – peritoneal catheter
- revision – laparoscopy – multiple adhesions

Case 5

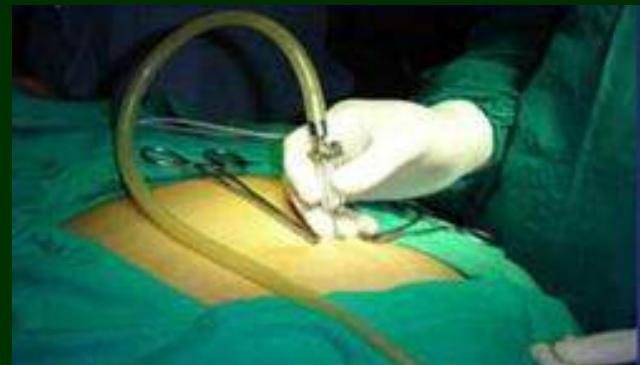

Case 5

- lesser trauma to the abdominal wall and peritoneum
- possibility of performing adhesiolysis and exquisite visualization of the peritoneal cavity, with in situ testing of catheter function
- lower risk of intraabdominal adhesions than laparotomy
- diagnosis of abdominal pain
- revision surgery
- primary placement

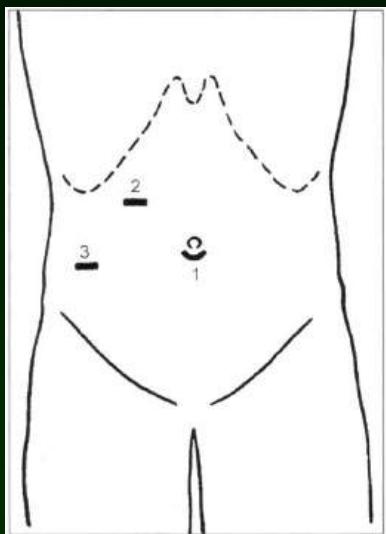

Case 5

- Laparoscopy is safe even without VP catheter clamping and with only routine anesthetic monitoring (Al-Mufarrej et al, 2005).
- Risk of retrograde failure minimal even with intraabdominal pressure as high as 80 mm Hg (Al-Mufarrej et al, 2005).

Case 5

Placement of trocars

X-ray after laparoscopic placement

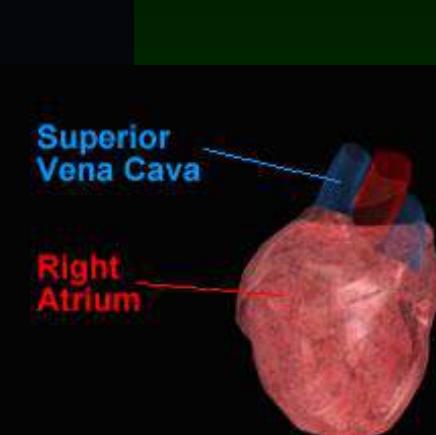

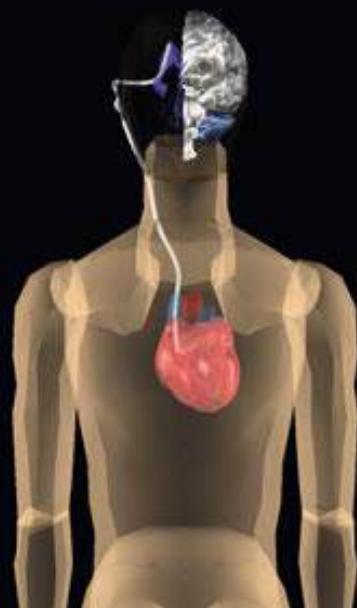

The end of the
peritoneal catheter

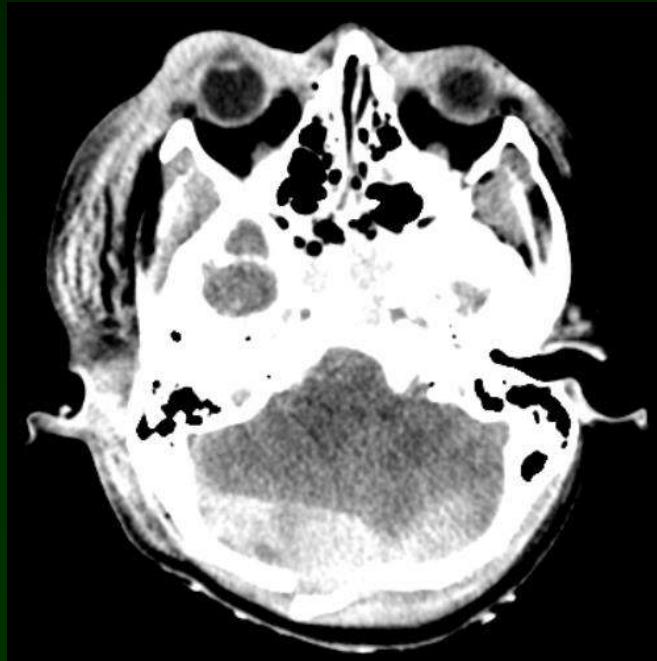

Case 5

- VA shunt

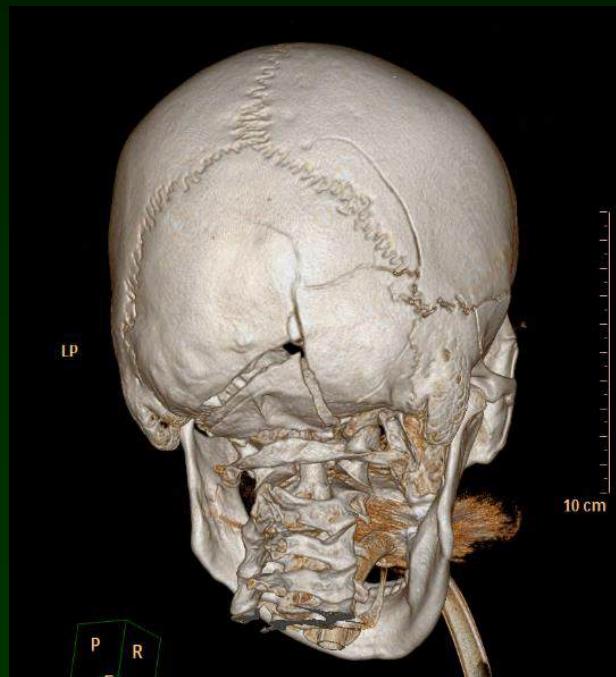

Case 6

- female, 26-year-old
- car accident, TBI, spine injury

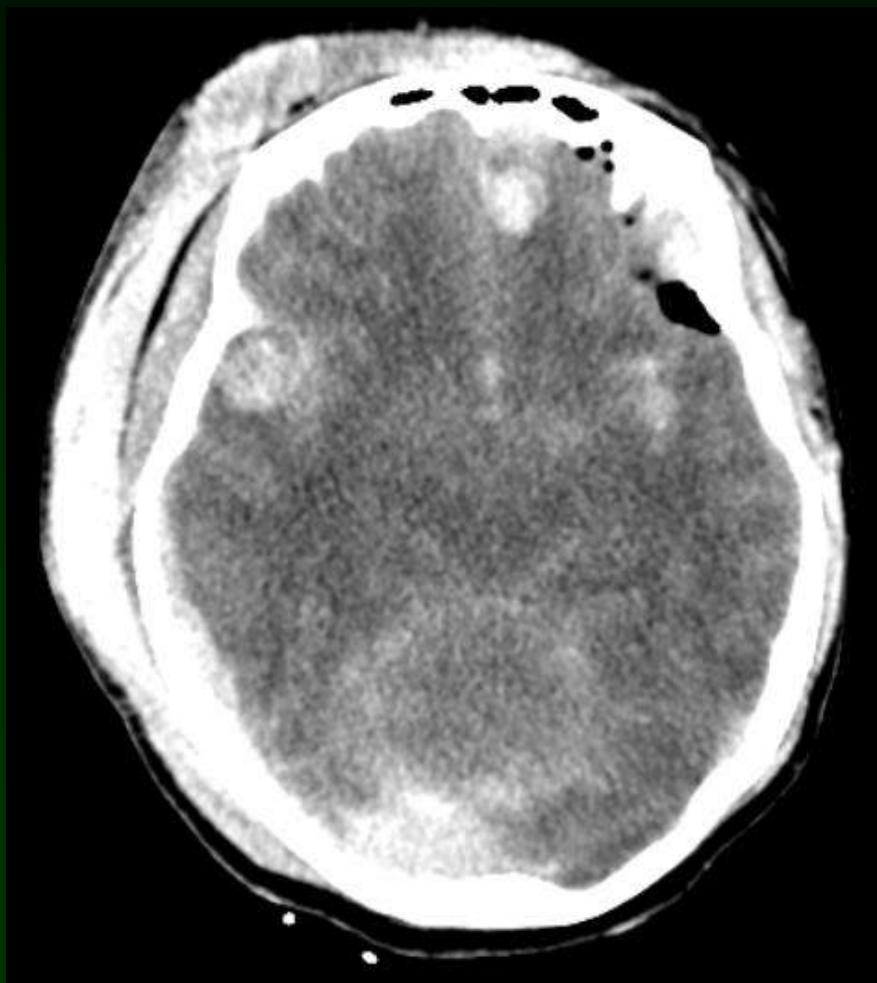

EDH

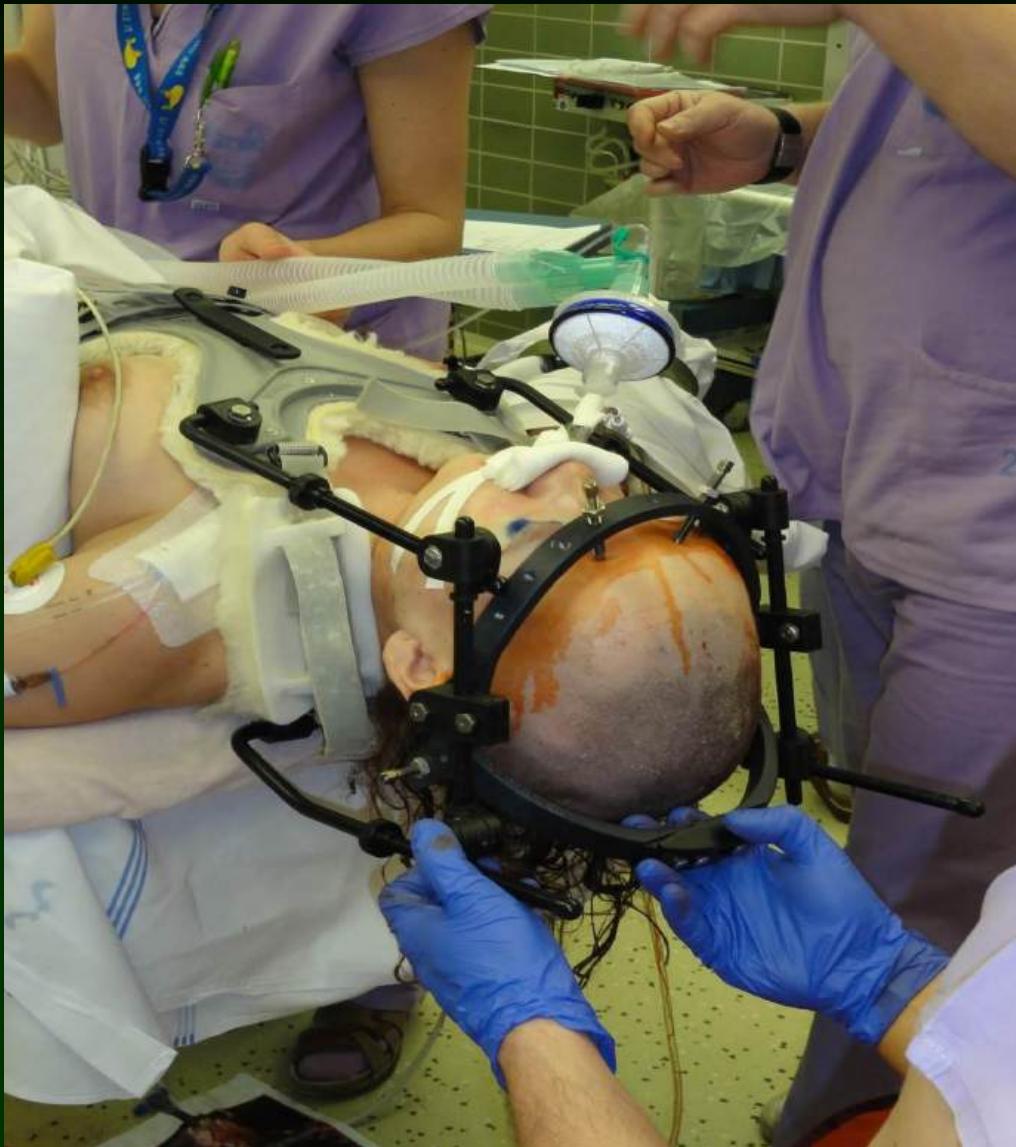

Occipital bone fracture,
subluxatio C0-1, C1-2

Case 6

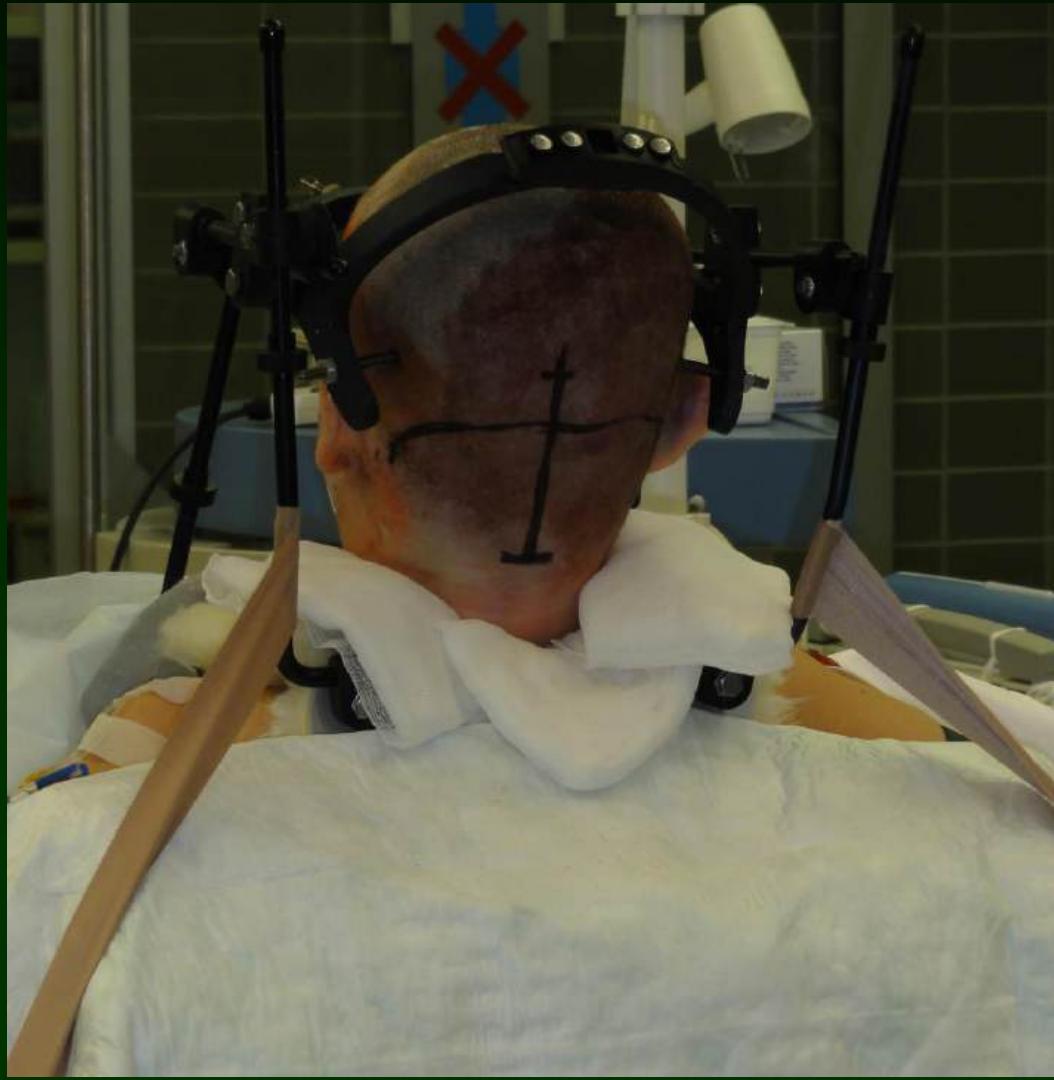

before operation, halo vest

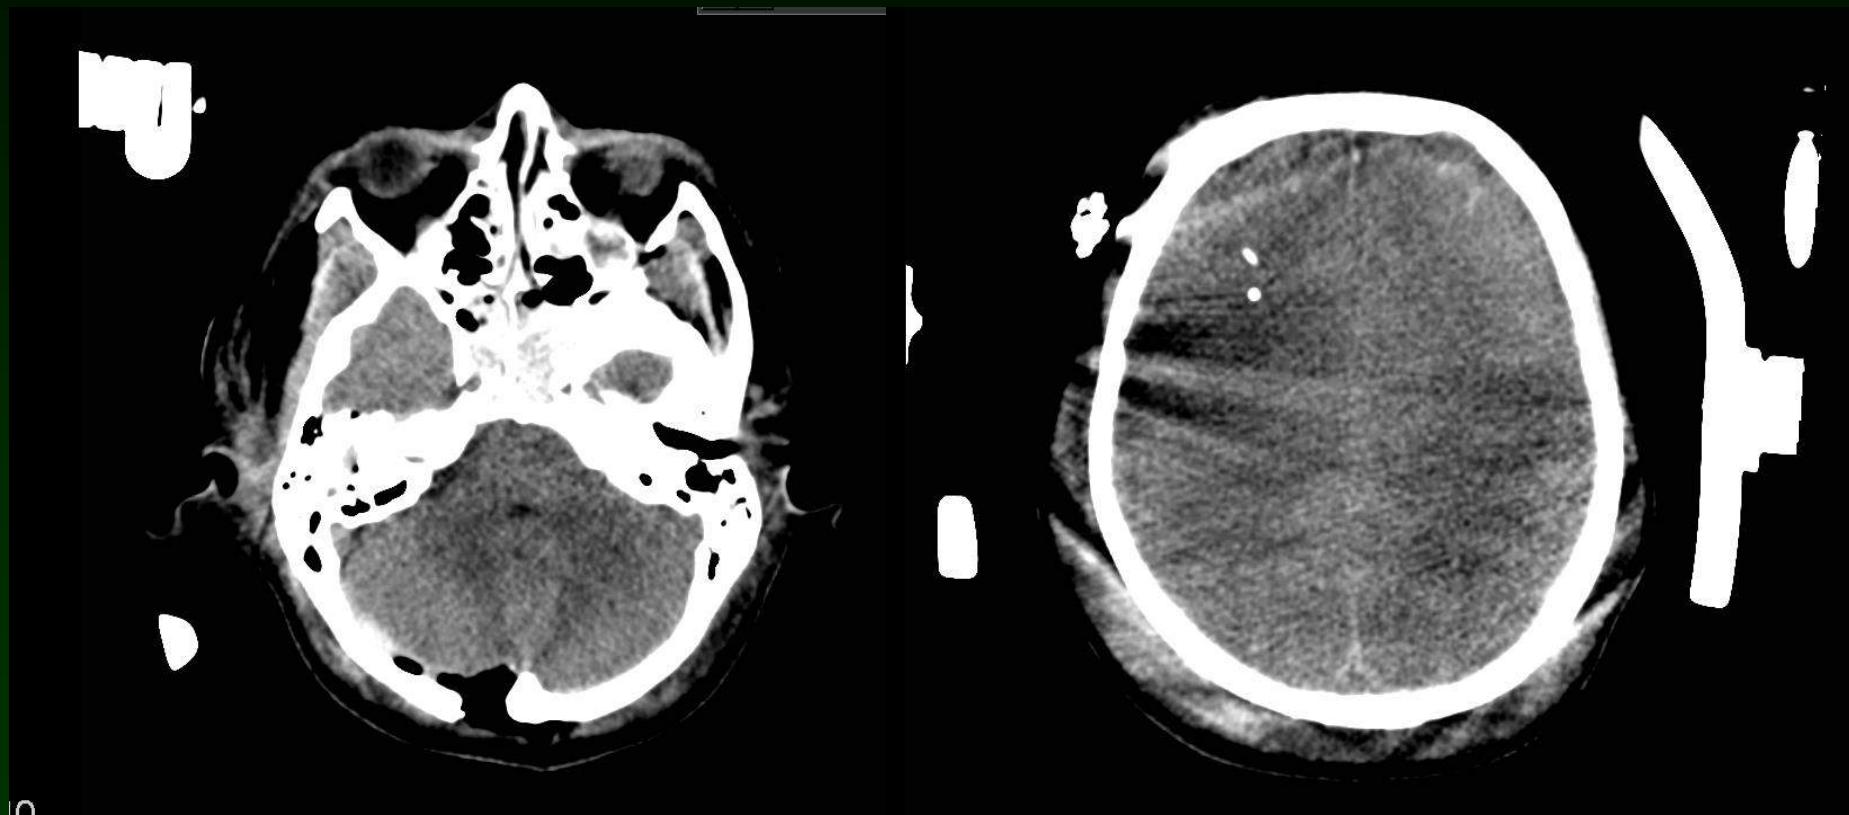

Case 6

Case 6

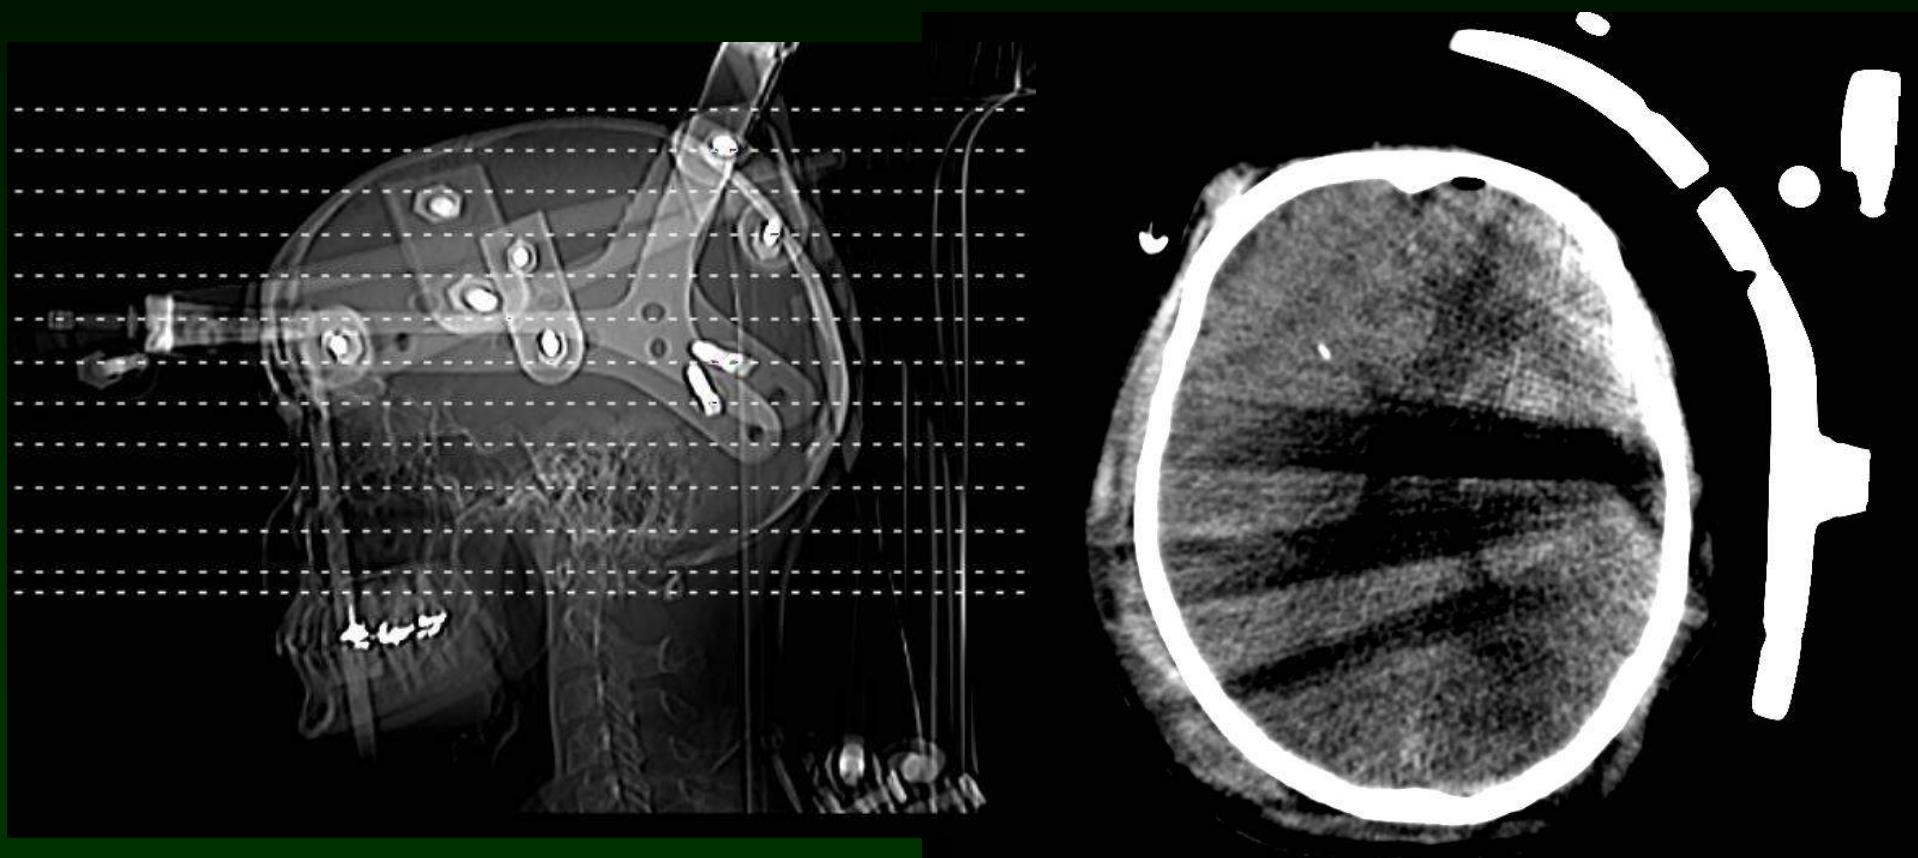

Case 6

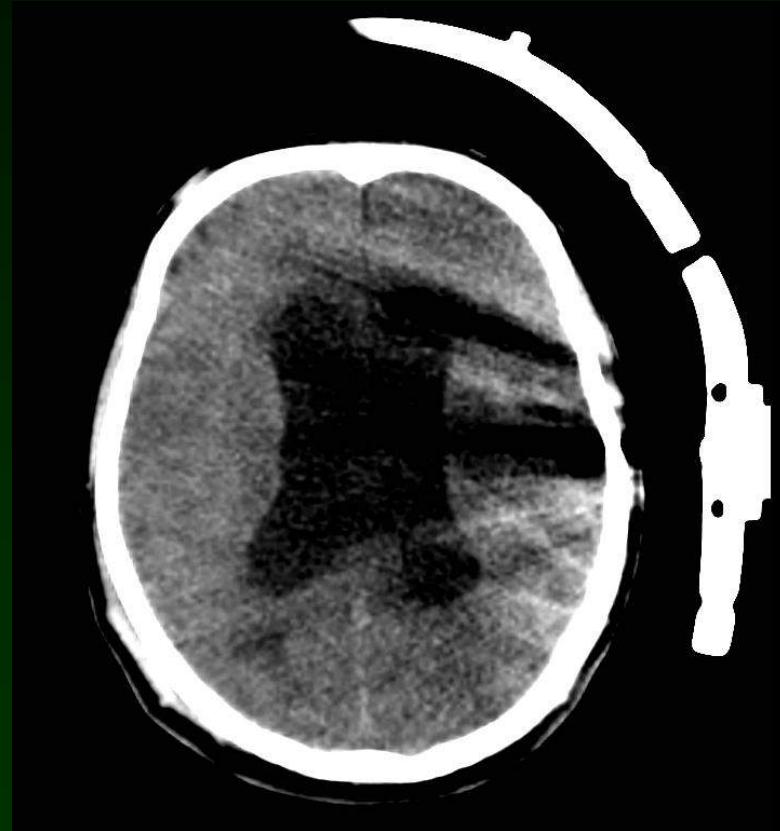

after operation

Case 6

after operation

Case 6

5 weeks later

Case 6

LP shunt

Case 6

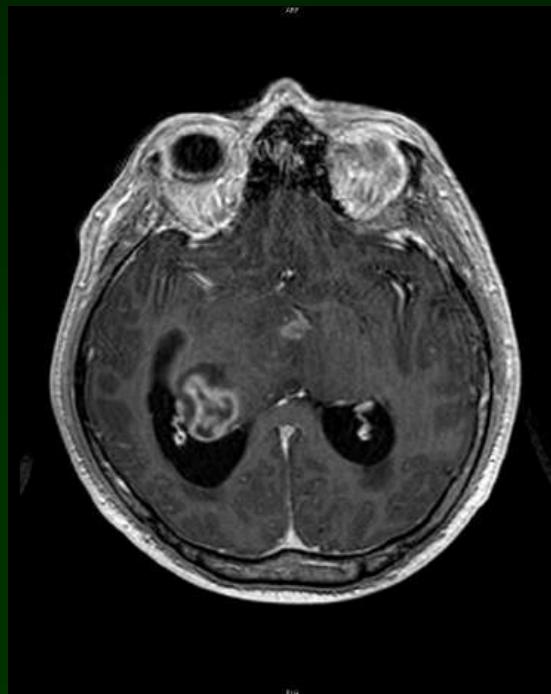

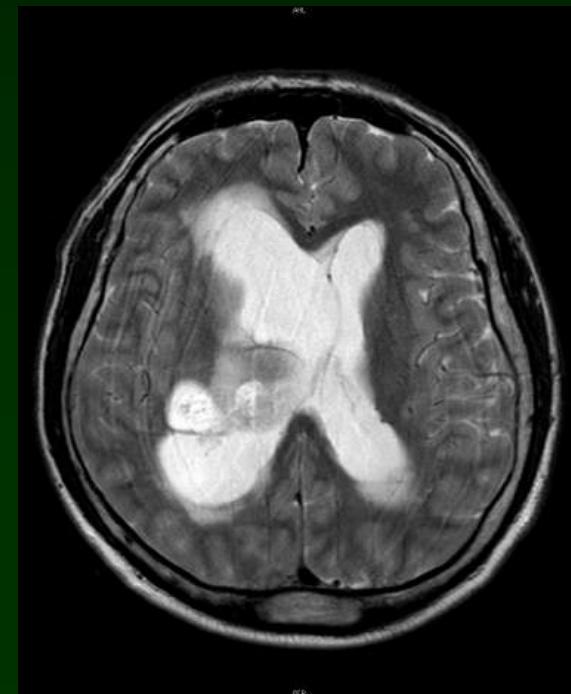

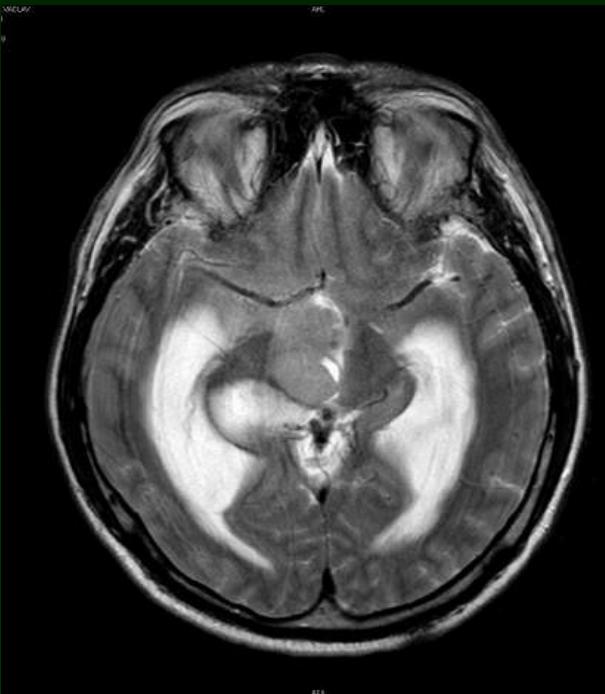

after LP shunt

Case 6

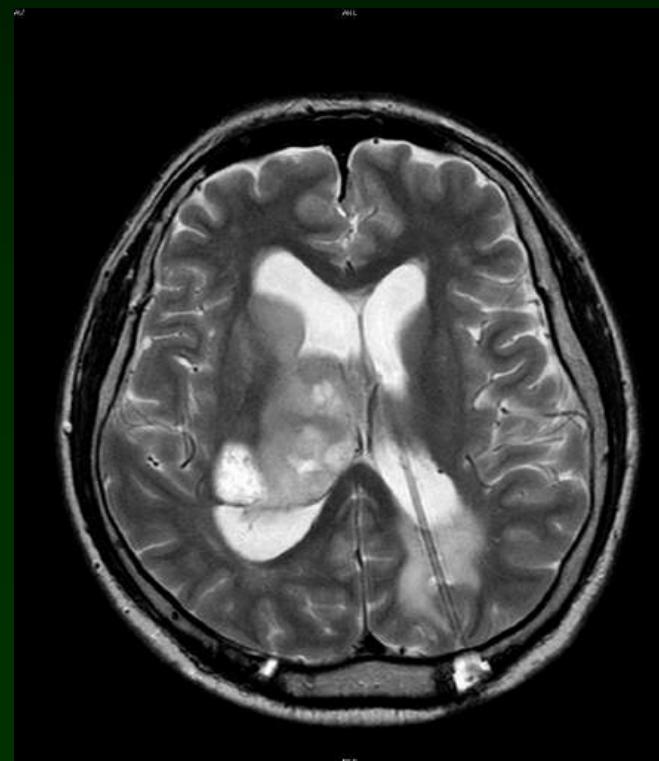

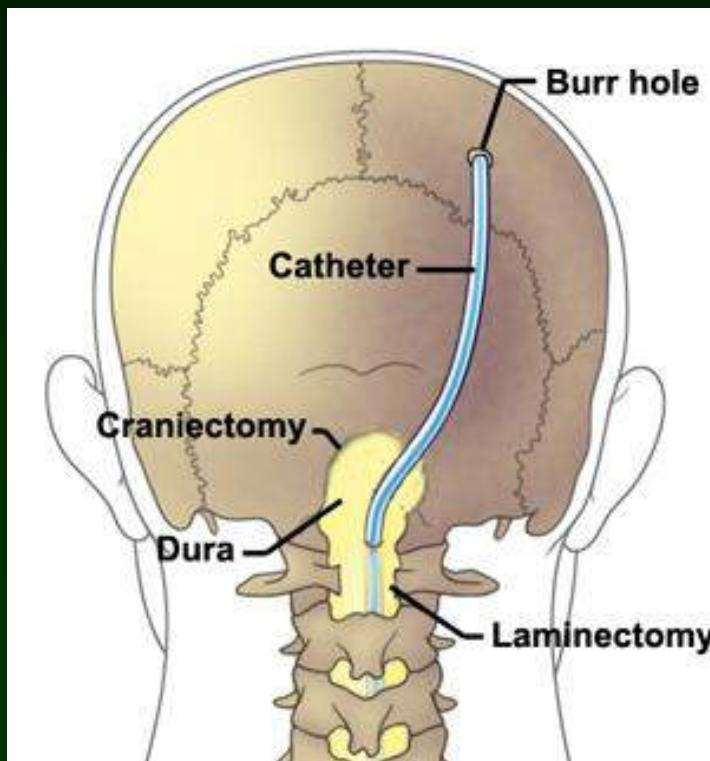

Case 7

- male, 50 years
- hydrocephalus
- tumour – biopsy - GBM

Case 7

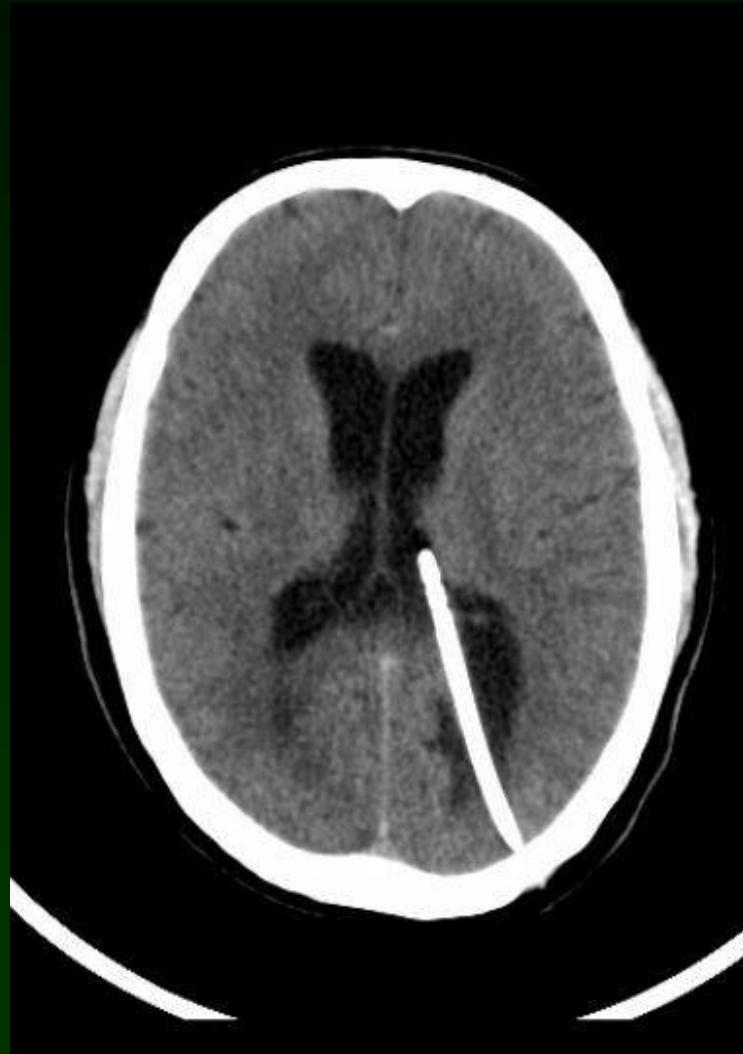

- Torkildsen drainage

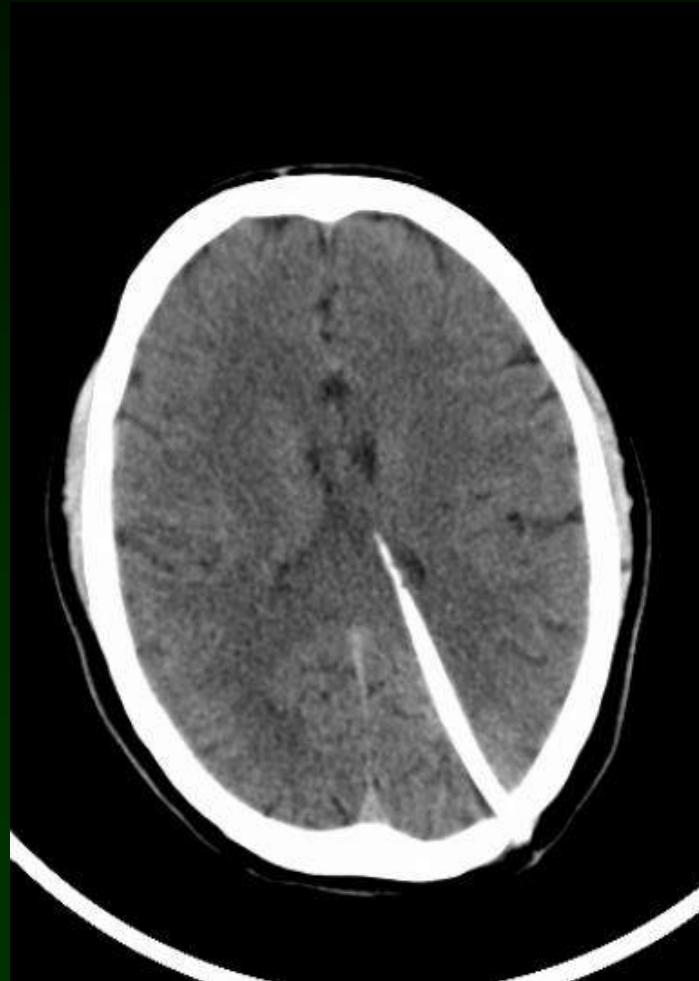

Case 8

- Male 25 years
- shunt surgery – 12 years + 4 additional revisions
- shunt malfunction – signs of intracranial hypertension

Case 8

Case 8

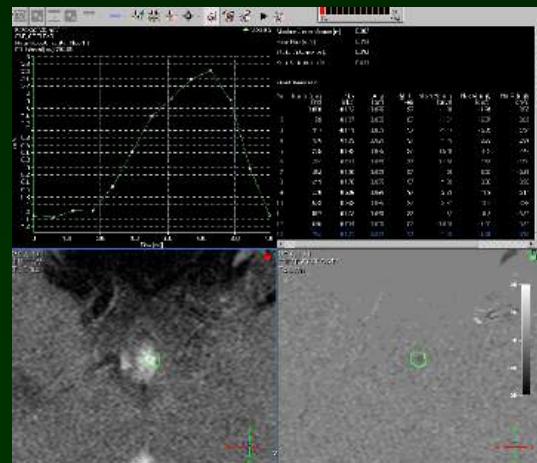

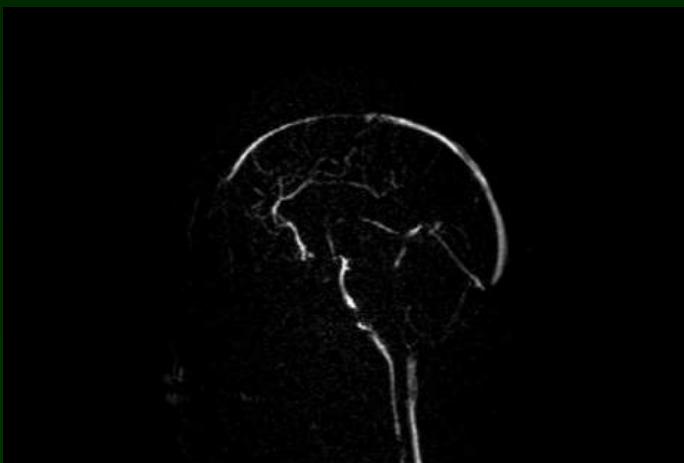

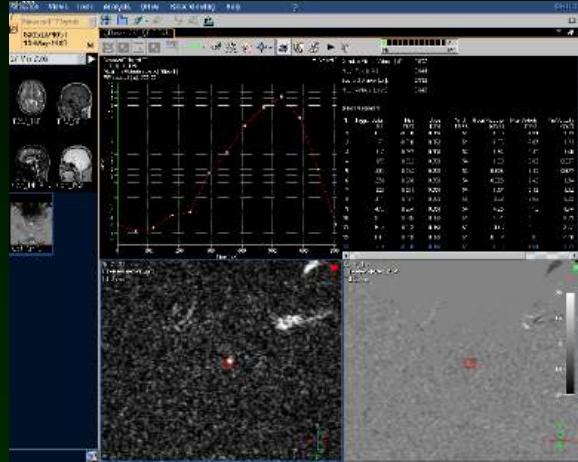

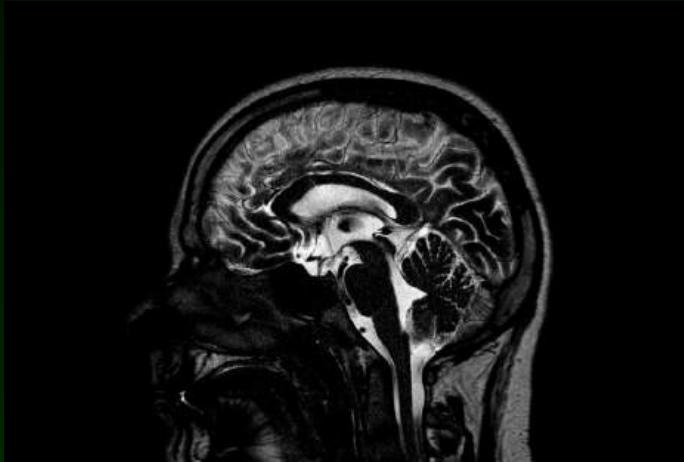

1 year ago

Case 8

Case 8

after operation

Case 9

- **Male - 51 years – headache, nausea, vomiting**
- **decreased consciousness, confusion, stiff neck**
- **CT exam – subarachnoid hemorrhage, acute hydrocephalus, DSA negative**
- **external ventricular drainage**

Case 9

Case 9

- Second DSA - negative
- implantation of a V-P shunt
- sepsis, meningitis, explanation of the V-P shunt, EVD
- Bacteriology negative, virology negative.

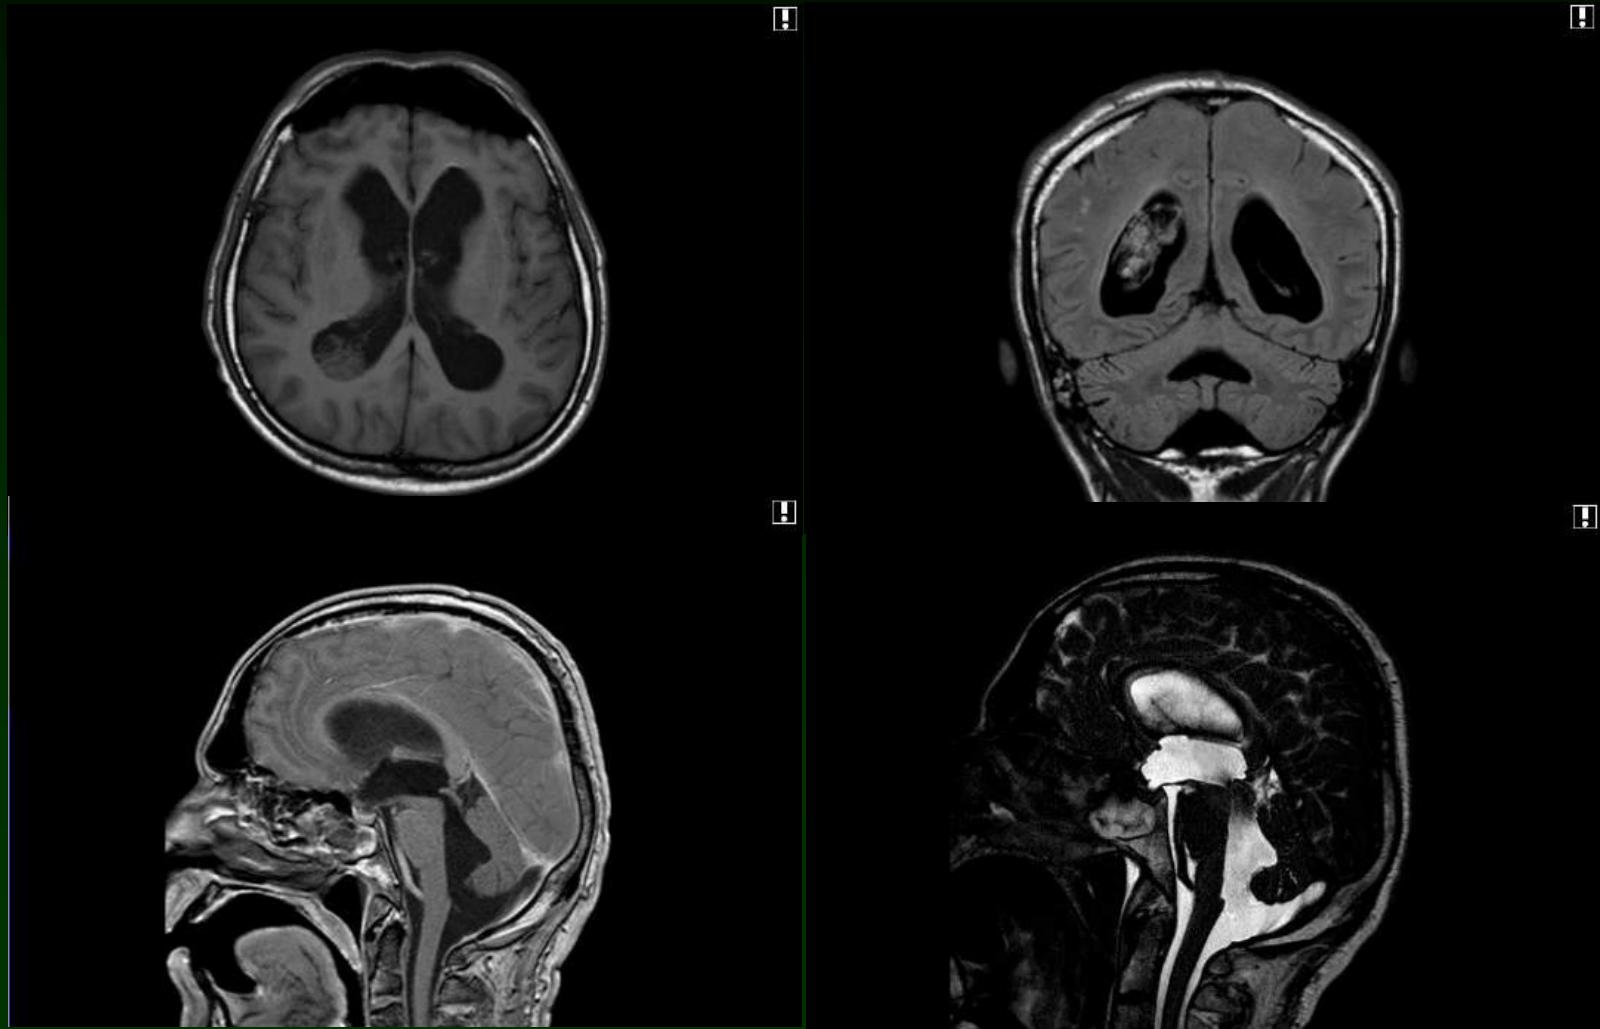

Case 9

- Rebleeding, IVH

Case 9

Case 9

- Another rebleeding

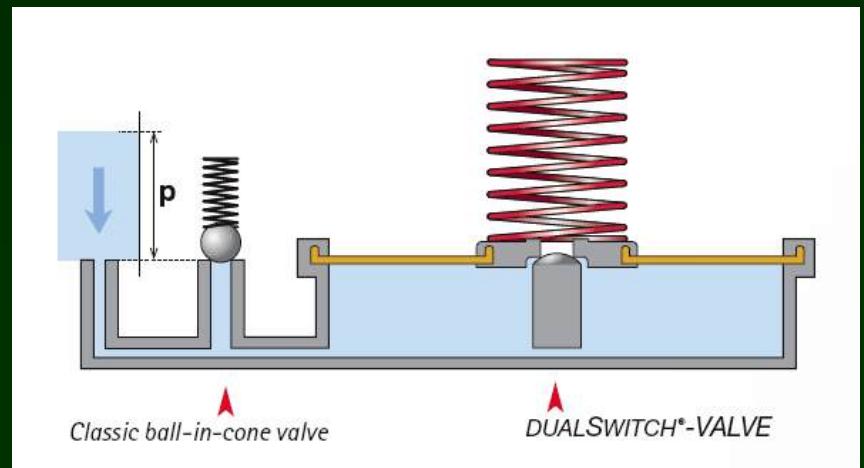

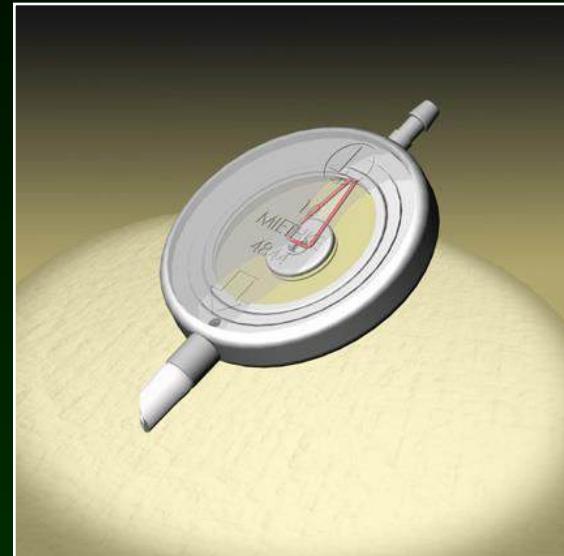

Case 9

- Monostep 10
- returned to work
 - businessman
- only slight organic syndrome

Case 9

- Monostep/Dualswitch
- a very large surface area to the CSF (overdrenage)
- mechanism effectively immune against any of the problems associated with proteins or blood

Case 9
